## Description

This invention relates to a class of spirocyclic piperidine derivatives which are selective ligands at sigma recognition sites and are therefore useful as neuroleptic agents.

Various spirocyclic piperidine derivatives are already known. For example, JP-A-55-143980 generically discloses inter alia a class of spiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] derivatives which are substituted on the ring nitrogen atom by hydrogen or by one of a range of hydrocarbon substituents. There is, however, no specific disclosure therein of a compound possessing a spiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] ring system. The compounds described in JP-A-55-143980 are stated to exhibit antiallergic activity. No suggestion is made in JP-A-55-143980 that the compounds described therein may be of any assistance in solving the problem of providing an effective agent for the treatment and/or prevention of psychiatric disorders.

US-3125580 describes inter alia the preparation of a class of spiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] derivatives. These compounds are variously N-substituted by a 3-cyano-3,3-diphenylpropyl or 3-alkanoyl-3,3-diphenylpropyl group. The compounds described in US-3125580 are stated to be potent analgesics with a relatively long duration of activity, and to possess mydriatic activity. There is no suggestion in US-3125580 that the compounds disclosed therein may be of any use as neuroleptic agents.

US-3125580 also discloses unsubstituted, N-cyano-substituted and N-benzyl-substituted spiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] derivatives as intermediates. One of the intermediates described in US-3125580, namely 1'-benzylspiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine], is stated in Chem. Pharm. Bull., 1984, 32, 3561, to have antiallergic activity via inhibition of histamine release. This document also describes the preparation of 1'-benzylspiro[1,4-dihydronaphthalene-1,4'-piperidine], but does not mention any therapeutic utility for this compound.

J. Med. Chem., 1978, 21, 474, and NIDA Research Monograph, 1987, Vol. 67 (Problems in Drug Dependency), pp. 453-489, "Evaluation of New Compounds for Opioid Activity (1985)", describe a range of spiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] compounds substituted on the nitrogen atom by a 3-substituted 3,3-diphenylpropyl group, which are stated to have analgesic activity.

A range of 1'-methylspiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] derivatives is described in Arch. Pharm. (Weinheim), 1987, 320, 385. No mention is made therein, however, of the possession of therapeutic utility by any of these compounds.

Indeed, nowhere in the prior art is there any suggestion that spiro[1,2,3,4-tetrahydronaphthalene-1,4'-piperidine] or spiro[1,4-dihydronaphthalene-1,4'-piperidine] derivatives may possess utility for the treatment and/or prevention of psychiatric disorders.

Most of the numerous currently available clinically effective antipsychotic drugs are dopamine D<sub>2</sub> receptor antagonists. As a result, they produce a characteristic spectrum of undesirable side-effects. These include endocrine effects and extrapyramidal side-effects, as well as often irreversible tardive dyskinesia. In addition, D<sub>2</sub> receptor antagonists are only palliative. They tend to alleviate only certain schizophrenic behaviour, especially the "positive" symptoms of florid delusions and hallucinations, with much less effect on the "negative" symptoms of emotional withdrawal.

From receptor binding studies, it has been shown that many effective neuroleptic agents are ligands at sigma recognition sites in the brain. Various compounds are known which are capable of interacting with the sigma recognition site, and it is considered that this interaction is significant in the manifestation of their neuroleptic properties. Most of these compounds, however, also display significant activity at the dopamine D<sub>2</sub> receptor and consequently elicit the undesirable side-effects referred to above. For example, haloperidol, a widely used neuroleptic agent, interacts equally potently with sigma sites and D<sub>2</sub> receptors.

One compound which is essentially inactive at dopamine D<sub>2</sub> receptors is rimcazole. However, whilst showing some antischizophrenic activity, rimcazole displays only moderate potency at sigma sites.

The analgesic compound N-allylnormetazocine (SKF 10047), whilst having an affinity for the sigma recognition site, also interacts strongly with the N-methyl-D-aspartate (NMDA) ion-channel complex, and thereby evokes a variety of psychotic symptoms including disorientation, excitement and hallucinations.

We have now found a class of potent, selective sigma receptor antagonists displaying negligible activity at D<sub>2</sub>, NMDA and other CNS receptors, which are therefore of value as neuroleptic agents.

The present invention accordingly provides the use of a compound of formula I or a pharmaceutically acceptable salt thereof:

The present invention further provides a "previously undisclosed compound of formula I" as defined above or a pharmaceutically acceptable salt thereof for use in therapy.

The pharmaceutical compositions of this invention are preferably in unit dosage forms such as tablets, pills, capsules, powders, granules, sterile parenteral solutions or suspensions, or suppositories, for oral, parenteral or rectal administration. For preparing solid compositions such as tablets, the principal active ingredient is mixed with a pharmaceutical carrier, e.g. conventional tableting ingredients such as corn starch, lactose, sucrose, sorbitol, talc, stearic acid, magnesium stearate, dicalcium phosphate or gums, and other pharmaceutical diluents, e.g. water, to form a solid preformulation composition containing a homogeneous mixture of a compound of the present invention, or a non-toxic pharmaceutically acceptable salt thereof. When referring to these preformulation compositions as homogeneous, it is meant that the active ingredient is dispersed evenly throughout the composition so that the composition may be readily subdivided into equally effective unit dosage forms such as tablets, pills and capsules. This solid preformulation composition is then subdivided into unit dosage forms of the type described above containing from 0.1 to about 500 mg of the active ingredient of the present invention. The tablets or pills of the novel composition can be coated or otherwise compounded to provide a dosage form affording the advantage of prolonged action. For example, the tablet or pill can comprise an inner dosage component, the latter being in the form of an envelope over the former. The two components can be separated by an enteric layer which serves to resist disintegration in the stomach and permits the inner component to pass intact into the duodenum or to be delayed in release. A variety of materials can be used for such enteric layers or coatings, such materials including a number of polymeric acids and mixtures of polymeric acids with such materials as shellac, cetyl alcohol and cellulose acetate.

The liquid forms in which the novel compositions of the present invention may be incorporated for administration orally or by injection include aqueous solutions, suitably flavoured syrups, aqueous or oil suspensions and flavoured emulsions with edible oils such as cottonseed oil, sesame oil, coconut oil or peanut oil, as well as elixirs and similar pharmaceutical vehicles. Suitable dispersing or suspending agents for aqueous suspensions include synthetic and natural gums such as tragacanth, acacia, alginate, dextran, sodium carboxymethylcellulose, methylcellulose, polyvinyl-pyrrolidone or gelatin.

In the treatment of psychiatric disorders, a suitable dosage level is about 0.01 to 250 mg/kg per day, preferably about 0.05 to 100 mg/kg per day, and especially about 0.05 to 5 mg/kg per day. The compounds may be administered on a regimen of 1 to 4 times per day.

The compounds of formula I above wherein A and B each represents hydrogen, including the novel compounds according to the invention, may be prepared by a process which comprises reducing a compound of formula III:

( III )

wherein R<sup>1</sup>, R<sup>2</sup> and R<sup>3</sup> are as defined above.

The ketone of formula III may conveniently be reduced directly to the corresponding compound of formula I wherein A and B each represents hydrogen by the Wolff-Kishner method. This comprises treating the hydrazone derivative of the ketone of formula III with a strong base, e.g. potassium hydroxide, in a suitable solvent, such as diethylene glycol, at an elevated temperature, preferably the reflux temperature of the solvent.

The intermediates of formula III above may conveniently be prepared by a method analogous to that described in *J. Org. Chem.*, 1966, **31**, 3345. This comprises reacting a compound of formula R<sup>1</sup>-N[(CH<sub>2</sub>)<sub>2</sub>Z]<sub>2</sub> with a β-tetralone derivative of formula IV:

( IV )

wherein R<sup>1</sup>, R<sup>2</sup> and R<sup>3</sup> are as defined above; and Z represents a leaving group, e.g. chlorine.

The β-tetralone derivatives of formula IV above, where they are not commercially available, can be prepared by the methods described in, for example, *Russ. Chem. Rev. (Engl. Transl.)*, 1966, **35**, 523; *J. Org. Chem.*, 1968, **33**, 4288; *Tetrahedron Lett.*, 1971, 951; or *J. Med. Chem.*, 1989, **32**, 961; or by methods analogous thereto.

The compounds of formula I above wherein A and B together represent a chemical bond, including the novel compounds according to the invention, may be prepared by a process which comprises dehydrating a compound of formula V:

( V )

wherein R<sup>1</sup>, R<sup>2</sup> and R<sup>3</sup> are as defined above.

A suitable dehydrating reagent for effecting the above conversion will, for example, be phosphorus oxychloride in the presence of pyridine.

The hydroxy intermediates of formula V above may conveniently be prepared by reduction of the keto group in the corresponding intermediate of formula III above using, for example, sodium borohydride under standard conditions.

An alternative process for preparing the compounds of formula I above, including the novel compounds according to the invention, comprises reacting a compound of formula R<sup>1</sup>-L with a compound of formula VI:

(VI)

wherein A, B, R<sup>1</sup>, R<sup>2</sup> and R<sup>3</sup> are as defined above; and L represents a leaving group.

The leaving group L is suitably halogen, for example bromine.

The reaction is conveniently carried out in the presence of a mild base such as potassium carbonate, in a suitable solvent, e.g. N,N-dimethylformamide, suitably at an elevated temperature, for example a temperature in the region of 100°C.

The compounds of formula VI above wherein A and B each represents hydrogen may be prepared by a process which comprises reducing a compound of formula VII:

(VII)

wherein R<sup>2</sup> and R<sup>3</sup> are as defined above, and R<sup>a</sup> represents an amino-protecting group; and subsequently removing the amino-protecting group R<sup>a</sup>.

An appropriate method for reducing the intermediate of formula VII is catalytic hydrogenation. A suitable catalyst is palladium hydroxide on charcoal, and the reaction is conveniently carried out in formic acid/ethanol as solvent.

Suitable examples of amino-protecting groups for the substituent R<sup>a</sup> include carboxylic acid groups such as acetyl, chloroacetyl, trifluoroacetyl, formyl, benzoyl, phthaloyl, phenylacetyl or pyridinecarbonyl; acid groups derived from carbonic acid such as ethoxycarbonyl, benzyloxycarbonyl, t-butoxycarbonyl, biphenylisopropoxycarbonyl, p-methylbenzyloxycarbonyl, p-nitrobenzyloxycarbonyl, p-bromobenzyloxycarbonyl, p-phenylazobenzyloxycarbonyl, p-(p'-methoxyphenylazo)benzyloxycarbonyl or t-amylloxycarbonyl; acid groups derived from sulphonic acid, e.g. p-toluenesulphonic acid; and other groups such as benzyl, trityl, o-nitrophenyl-

sulphenyl or benzylidene.

Preferred amino-protecting groups are benzyl, benzyloxycarbonyl and t-butoxycarbonyl.

The removal of the amino-protecting group present in the resultant compound may be effected by an appropriate procedure depending upon the nature of the protecting group. For example, if R<sup>a</sup> represents benzyl this group may be removed *in situ* during hydrogenation of the intermediate of formula VII.

The intermediates of formula VII above may be prepared by appropriate variation of the method described in *Chem. Pharm. Bull.*, 1984, **32**, 3561. The synthetic route commences from a  $\beta$ -tetralone derivative of formula IV above and may be illustrated as follows:

in which R<sup>2</sup>, R<sup>3</sup> and R<sup>a</sup> are as defined above.

During any of the above synthetic sequences it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in *Protective Groups in Organic Chemistry*, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene, *Protective Groups in Organic Synthesis*, John Wiley & Sons, 1981. The protecting groups may be removed at a convenient subsequent stage using methods known from the art.

Displacement of Tritiated Sigma LigandIn vitro activity

- 5 Binding of test compounds to the sigma site in vitro was determined by the method of Weber *et al.*, Proc. Natl. Acad. Sci. USA, 1986, **83**, 8784. The compounds of each of the accompanying Examples displaced tritiated di-tolyl guanidine (DTG) from sigma sites with potencies better than 200 nM.

In vivo activity

- 10 The ability of the test compounds to displace tritiated sigma ligands in vivo was determined by a modification of the method of Ferris *et al.*, Life Sci., 1986, **38**, 2329. In these experiments the sigma ligand used was tritiated (+)-SKF 10047. The compounds of accompanying Examples 2 and 3 were tested and showed an effective dose for displacing 50% of ligand (ED<sub>50</sub>), following s.c. dosing, of better than 1.0 mg/kg in each case.

EXAMPLE 11'-Benzylspiro[1,4'-dihydronaphthalene-1,4'-piperidine]

- 20 Step 1: 1,1-Bis(methoxycarbonylmethyl)-2-tetralone

- To a stirred solution of 2-tetralone (15g, 0.1mol) and methyl bromoacetate (47g, 0.31mol) in toluene (50ml) at 0°C, under nitrogen, was added sodium hydride (7.3g of an 80% dispersion in mineral oil, 0.24mol) portionwise. After addition of the base the reaction mixture was stirred at room temperature for 18 hours. Glacial acetic acid (18ml) was then added, followed by a few drops of concentrated hydrochloric acid and water (30ml). The mixture was then extracted with ether (3 x 200ml), and the combined ethereal layers washed with saturated sodium bicarbonate solution (2 x 70ml) and water (70ml). The organic phase was separated, dried (MgSO<sub>4</sub>) and solvents removed in vacuo. The resulting orange solid was recrystallised from 1:1 petrol (60/80):ether, to give 1,1-bis(methoxycarbonylmethyl)-2-tetralone (16.9g, 57%) as white needles. m.p. 84-86°C NMR (CDCl<sub>3</sub>) δ 2.90 (4H, m), 3.19 (4H, m), 3.50 (6H, s), 7.19 (4H, s). m/z (EI) 290 (M<sup>+</sup>), 259, 216, 184, 157, 128, 91, 77.

Step 2: 1,2,3a,4,5,9b-Hexahydro-9b-(methoxycarbonylmethyl)naphtho[2,1-b]furan-2-one.

The solution was stirred for 3 hours, then the ethanol was removed in vacuo, and the residue taken up in ethyl acetate (30ml). The organic layer was washed with water (30ml), then dried (MgSO<sub>4</sub>) and the ethyl acetate removed in vacuo. The residue was chromatographed in 1:1 petrol (60/80):ether, to give 1,2,3a,4,5,9b-hexahydro-9b-(methoxycarbonylmethyl)naphtho[2,1-b]furan-2-one (0.35g, 48%) as a viscous colourless oil.
